Residential Buildings

Subsector Summary
The residential buildings subsector encompasses all GHG emitting activities from energy use in households\(^1\) including heating, cooking, and lighting. The two primary categories of GHG emitting activities within the subsector are: scope 1) emissions from fuel combustion associated with residential buildings within the community boundary and scope 2) emissions from consumption of grid-supplied electricity (which may be generated outside the community boundary).

Inclusions:
For Indonesia, based on data availability and country-specific relevance, estimates for the following activity data points are produced:

- **Liquid Petroleum Gas** used by households, based on annual fuel consumption by residential customers at national level.
- **Kerosene** used by households, based on annual fuel consumption by residential customers at province level.
- **Grid-supplied Electricity** used by households, based on annual electricity consumed by residential customers at the province level.

Exclusions:
Due to lack of data availability and country-specific relevance, estimates for the following activity data points are not produced:

- **Off-highway motor gasoline** consumption, e.g. for use in lawn and gardening equipment
- **District heating, cooling**, or other non-electricity grid-supplied energy

Activity Data Coverage
The specific data points and energy sources covered by the methodology are outlined in the table below.

<table>
<thead>
<tr>
<th>Fuels/Energy Source</th>
<th>GHGDP Definition</th>

<td>MJ</td>
<td>Scope 2</td>
</tr>
</tbody>
</table>
Calculations Methodologies:

Scope 1: Liquid Petroleum Gas (LPG)

**Methodology Notes**

Residential building LPG consumption is calculated from Indonesia’s National Energy Balance data for the year 2017 from the Handbook of Energy & Economic Statistics Indonesia published by Ministry of Energy & Mineral Resources. The initial input data is allocated to communities based on the number of households in the municipality using LPG relative to the national household total using LPG.

Total national count of households and total households by municipality using LPG are sourced from the Census data by Badan Pusat Statistik (BPS) Indonesia for the year 2010.

The following equation is utilized to estimate household kerosene consumption.

**Equation 1: Household LPG Consumption**

\[
\text{Community scale Household Consumption} = \text{Aggregate Fuel Sales}_{\text{National}} \times \left( \frac{\text{No. of Households using LPG}_{\text{Community}}}{\text{No. of Households using LPG}_{\text{National}}} \right)
\]

**Equation Data Elements**

<table>
<thead>
<tr>
<th>Data element</th>
<th>Description</th>
<th>Source</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>Community scale Household Consumption</td>
<td>All LPG consumption within community boundary for a single year for all households.</td>
<td>Equation 1</td>
<td>MJ</td>
</tr>
<tr>
<td>Aggregate Fuel Sales(_{\text{National}})</td>
<td>Amount of fuel distributed to residential customers within entire country</td>
<td>Indonesia Energy Balance 2017</td>
<td>MJ</td>
</tr>
<tr>
<td>(\frac{\text{No. of Households using LPG}<em>{\text{Community}}}{\text{No. of Households using LPG}</em>{\text{National}}})</td>
<td>Ratio representing the number of households within community using LPG over the number of households in the country using LPG</td>
<td>BPS 2010</td>
<td>households</td>
</tr>
</tbody>
</table>

**Methodology Assumptions**
General assumptions and limitations

- All households that use LPG within a community use the same quantity of LPG
- LPG consumption within the residential sector is mainly for cooking purposes
- For the purpose of this methodology, we only accessed community-specific household data from the 2010 census. Improvements to this method can be made when a more recent census is released.
- National Energy Balance totals are assumed to encompass all LPG national residential consumption

Scope 1: Kerosene

**Methodology Notes**
Residential building Kerosene consumption is taken from Indonesia’s Oil and Gas Regulatory data for Fuel sales by sector by province for the year 2017. The initial input data is allocated to communities based on the number of households in the municipality relative to the state totals.

Total count of households by province and total households by municipality are sourced from the Census data by Badan Pusat Statistik (BPS) Indonesia for the year 2010.

The following equation is utilized to estimate household kerosene consumption.

**Equation 2: Community Kerosene Consumption**

\[
\text{Community scale Household Consumption} = \text{Aggregate Fuel Sales}_{\text{Province}} \times \left( \frac{\text{No. of Households}_{\text{Community}}}{\text{No. of Households}_{\text{Province}}} \right)
\]

**Equation Data Elements**

<table>
<thead>
<tr>
<th>Data element</th>
<th>Description</th>
<th>Source</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Community scale Household Consumption</td>
<td>All Kerosene consumption within community boundary for a single year for all households.</td>

</tr>
<tr>
<td>(\frac{\text{No. of Households}<em>{\text{Community}}}{\text{No. of Households}</em>{\text{Province}}})</td>
<td>Ratio representing the households within community over the number of households in the</td>
<td>BPS 2010</td>
<td>households</td>
</tr>
</tbody>
</table>
Methodology Assumptions

General assumptions and limitations

- All households within a community use the same quantity of kerosene
- For the purpose of this methodology, we only accessed community-specific household data from the 2010 census. Improvements to this method can be made when a more recent census is released.
- Oil and Gas Regulatory totals are assumed to encompass all kerosene national residential consumption.

Scope 2: Electricity

Methodology Notes

Residential building electricity consumption is taken from Indonesia’s Electricity Statistics Handbook by province for the year 2017. The initial input data is allocated to communities based on the number of households in the municipality relative to the state totals.

Total count of households by province and total households by municipality are sourced from the Census data by Badan Pusat Statistik (BPS) Indonesia for the year 2010.

The following equation is utilized to estimate household electricity consumption

**Equation 3: Community Electricity Consumption**

\[
\text{Community scale Household Consumption} = \text{Aggregate Electricity Consumption}_{\text{Province}} \times \left( \frac{\text{No. of Households}_{\text{Community}}}{\text{No. of Households}_{\text{Province}}} \right)
\]

**Equation Data Elements**

<table>
<thead>
<tr>

<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Community scale Household Consumption</em></td>
<td>All electricity consumption within community boundary for a single year for all households.</td>
<td>Equation 3</td>
<td>MJ</td>
</tr>
</tbody>
</table>
Methodology Assumptions

- All households use the same quantity of electricity within a community.
- For the purpose of this methodology, we only accessed community-specific household data from the 2010 census. Improvements to this method can be made when a more recent census is released.
- Electricity Statistics totals are assumed to encompass all electricity residential consumption in the country.

Emission Factors

Commercial Buildings

Subsector Summary
The commercial buildings subsector encompasses all GHG emitting activities from energy use in
commercial buildings, including heating, cooling, and lighting. The two primary categories of GHG
emitting activities within the subsector are: scope 1 emissions from fuel combustion associated with
commercial buildings within the community boundary and scope 2 emissions from consumption of grid-
supplied electricity.

Inclusions:
For Indonesia, based on data availability and occurrence in-country, estimates for the following activity
data points are produced:

- **Grid-supplied electricity** used by commercial businesses, based on annual electricity consumed
  by commercial customers at the national level.

Exclusions:
Due to lack of data availability or occurrence in-country, estimates for the following activity data points
are not produced:

- **Off-highway motor gasoline** consumption, e.g. for use in landscaping equipment
- **District heating, cooling**, or other non-electricity grid-supplied energy
- **Natural gas, liquefied petroleum gas**, and **diesel oil** used by commercial buildings, based on
  annual fuel consumption by customers at national level.

Activity Data Coverage
The specific data points and energy sources covered by the methodology are outlined in the table below.

</tbody>
</table>
Calculation Methodologies

Scope 2: Electricity

**Methodology Notes**

Commercial building electricity consumption is taken from Indonesia’s Electricity Statistics Handbook for the year 2017. This initial input data is allocated to communities based on the proportion of employees in the community relative to the province totals.

Total count of employees by province and total employees by municipality for the commercial sector is sourced from the Census data by Badan Pusat Statistik (BPS) Indonesia for the year 2010.

The following equation is utilized to estimate commercial electricity consumption.

**Equation 4: Community Electricity Consumption**

\[
\text{Community scale Commercial Consumption} = \text{Aggregate Electricity Consumption}_{\text{Province}} \times \left( \frac{\text{Sector Employees}_{\text{Community}}}{\text{Sector Employees}_{\text{Province}}} \right)
\]

**Equation Data Elements**

<table>
<thead>
<tr>
<th>Data element</th>
<th>Description</th>
<th>Source</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>Community scale Commercial Consumption</td>
<td>Electricity consumption within community boundary for a single year for all commercial buildings</td>
<td>Equation 4</td>
<td>MJ</td>
</tr>
<tr>
<td>Aggregate Electricity Consumption (\text{Province})</td>
<td>Amount of fuel distributed to commercial customers within entire province</td>
<td>BPS 2017</td>
<td>MJ</td>
</tr>
<tr>
<td>(\frac{\text{Sector Employees}<em>{\text{Community}}}{\text{Sector Employees}</em>{\text{Province}}})</td>
<td>Calculated ratio representing the estimated number of commercial sector employees within the community over the estimated state province</td>
<td>BPS 2010</td>
<td>employees</td>
</tr>
</tbody>
</table>
Methodology Assumptions

- Number of commercial sector employees is proportionally related to the size of a commercial facility which is in turn proportional to the amount of electricity consumed.
- Electricity Statistics numbers are assumed to encompass all electricity national commercial consumption.
- All electricity sold to commercial customers is consumed within the year it is delivered.

Emission Factors

The following table provides IPCC 2006 emission factor values for the list of fuels used in the buildings and stationary sector methodology for Indonesia.

<table>
<thead>
<tr>
<th>Fuel type</th>
<th>Carbon Dioxide (CO2) kg/GJ</th>

</tr>
</tbody>
</table>
On-Road

Subsector Summary
GHG emissions within the On-Road subsector result from the consumption of fuel for on-road vehicles such as passenger cars, light trucks, motorcycles, mopeds, buses, heavy trucks, and combination trucks within a community boundary. The GHG emitting activity we focus on in this subsector is fuel consumption (scope 1) from fuels such as gasoline and diesel.

Inclusions
For Indonesia, based on available data and method, activity data produced includes:

- **Gasoline** and **diesel fuel** sales for passenger cars, trucks, motorcycles, and buses

Exclusions
Due to lack of data, this methodology does not include:

- Fuel consumption disaggregated by fleet type from all on-road vehicles.
- The vehicle kilometers traveled by all on-road vehicles.

Activity Data Coverage
Table 1 includes the emissions sources covered by this methodology.

<table>
<thead>
<tr>
<th>Emissions Source</th>

<td>Scope 1</td>
</tr>
<tr>
<td>Diesel</td>
<td>The amount of diesel consumed for a single year by all vehicles in a community boundary</td>
<td>Liters</td>
<td>Scope 1</td>
</tr>
</tbody>
</table>

Allocation Methodology

Fuel Consumption
The input data from the Oil and Gas Regulatory provides province values for gasoline and diesel sales by all on-road vehicles. This dataset therefore required additional disaggregation to be completed using the total number of vehicle registrations by municipality in our methodology.

In Indonesia, there are several gasoline types namely RON 88, RON 90, RON 92, RON 95, RON 98. All these gasoline types were summed together and represented as total province gasoline value. Solar CN 51 and Solar CN 53 are types of diesel which are summed and broadly represented under total province diesel value. These are then disaggregated by vehicle type for each community.
Equation 1 includes the approach used to estimate gasoline and diesel sales for vehicle types.

**Equation 1: Community fuel sales**

\[
\text{Community fuel sales}_{\text{vehicle type}} = \text{Province fuel sales}_{\text{vehicle type}} \times \frac{\text{Municipality vehicle registrations}_{\text{vehicle type}}}{\text{Province vehicle registrations}_{\text{vehicle type}}}
\]

**Table 2 – Data sources to estimate gasoline consumption**

<td>Vehicles</td>
<td>BPS, Province Regional Police (2014 – 2017)</td>
</tr>
</tbody>
</table>

**Methodological and Data Assumptions & Limitations**

This methodology assumes that:

- Gasoline and diesel are the only fuels used by vehicles.
- All motorcycles use gasoline, passenger cars use either gasoline (80%) or diesel (20%), all buses and trucks use diesel. It is assumed that 80% of registered passenger cars use gasoline, and that 20% use diesel (Clean Air Asia, 2018)
- Without average fuel consumption by vehicle type, it is assumed that the disaggregation is proportional to the number of vehicles in each vehicle type.
• All trucks are categorized as single-unit trucks because no additional information was available about type of truck.
• It is assumed that motorcycles and cars use all the gasoline subtypes (summed to represent total gasoline value) in equal proportions.
• It is assumed that cars, trucks and buses all use the diesel subtypes (summed to represent total diesel value) in equal proportions.

Emission Factors
This methodology uses emission factors from the IPCC *Guidelines for National Greenhouse Gas Inventories Volume 2: Energy* (IPCC, 2006). These are globally recognized default emission factor values. Table 2 includes the fuels used in Indonesia and their corresponding emission factor values.

Solid Waste

Subsector Overview

This section covers the activity data and emission factors needed for communities in Indonesia to estimate emissions from the disposal of municipal solid waste (MSW). While other gases are also emitted through the collecting, sorting, and transporting of solid waste to treatment facilities—namely biogenic carbon dioxide, non-methane volatile organic compounds, and nitrous oxide—this methodology focuses on estimating values related to MSW treated at landfill facilities or open dumps only. If desired, communities may consult international resources such as the IPCC guidelines for national reporting or local guidance documents, if available, to estimate non-methane GHG emissions from solid waste disposal. Hence, emissions under this sub-sector are influenced by the following five factors:

1) The mass of community-generated waste disposed in landfills or open dumps;
2) The methane generation potential
3) The methane correction factors; influenced by waste composition
4) The oxidation factors
5) The amount of methane recovered (for facilities with existing technology to do so).

Methane (CH₄) is the main gas emitted during the MSW treatment processes. The following section discusses methods for estimating the mass of waste, methane correction factor, oxidation factor and methane recovery fraction—where applicable—at a community level. All of these variables impact the final total of methane emissions reported in Indonesia.

Inclusions

For Indonesia, based on available data, this methodology provides estimates on:

- Community-specific mass of waste landfilled at landfill facilities
- Methane Correction Factor based on historical landfill management characteristics such as managed, unmanaged deep, unmanaged shallow, and uncategorized landfills.
- Methane Generation Potential (L₀) based on degradable organic carbon, landfill management type and fraction of methane in landfill gas nationally.
- Oxidation Factors (OX) based on waste disposal management practice.

Exclusions

Due to the unavailability of data, the methods exclude:

- Community-specific mass of industrial, sludge, clinical, and fossil liquid waste.
- Landfill methane recovery fraction at landfill facilities with recovery systems in place.
The combustion, or flaring, of landfill gas for non-energy purposes

The combustion of solid waste for non-energy purposes

Calculation Methodology

Activity Data – Mass of Waste (Managed Landfills)
Municipal solid waste data at a province level is obtained from the Ministry of Public Works as published in the Information Statistics Book for the year 2017. The community population from the Census data is obtained from Badan Pusat Statistik (BPS) Indonesia. The community-specific mass of waste is calculated as per the following equation.

\[ \text{Landfilled Waste}_{\text{Community}} = \frac{\text{Landfilled Waste}_{\text{Province}} \times (\text{Community Population}/\text{Province Population})}{\text{Province Population}} \]

Data Element | Definition | Units | Data Source |
|--------------|------------|-------|-------------|

1 While the flaring of landfill gas is typically reported under the waste sector, to burning of landfill gas for energy purposes is reported under the stationary energy sector

2 Similar to above, the burning of waste for non-energy purposes falls under the waste sector, whereas any waste burned for energy (e.g. heat or electricity generation) falls under the stationary energy sector
Landfilled Waste\textsubscript{Community} | Mass of community-generated organic waste going to landfills | Tonnes | Equation 1  
Landfilled Waste\textsubscript{Province} | Mass of state-generated organic waste going to landfills | Tonnes | Ministry of Public Works, Indonesia (2017)  
Community Population | Total number of residents living within community boundary | People | Indonesia Census (2010)  
Province Population | Total number of persons living in the state | People | Indonesia Census (2010)  

Methane Correction Factor (MCF)
Since CH\textsubscript{4} generation rates are dependent on landfill management practices, this methodology uses the IPCC (2006) default landfill management types to determine an appropriate community-specific methane correction factor. IPCC (2006) assigns a unitless MCF value of 1 for managed landfills and 0.4 for Unmanaged Shallow Landfills. Since there is no information on the type of Landfills in Indonesia a weighted MCF is created by taking the mean of the above factors, yielding an MCF value of 0.7.

Methane Generation Potential (L\textsubscript{0})
Methane generation potential (L\textsubscript{0}) is itself a combination of several components: The Methane Correction Factor (MCF); Degradable Organic Carbon (DOC), weighted by waste stream type (discussed below); the fraction of waste degraded anaerobically (DOC\textsubscript{F}); the fraction of landfill gas that is methane (F); and the methane to carbon ratio. In the absence of facility-specific data, each of these values is derived from IPCC 2006 list of default values. This methodology calculates the methane generation potential of landfilled waste in Indonesia using equation below:

\[
L_0 = MCF \times DOC \times DOC_F \times F \times \frac{16}{12}
\]

Table 3: Data elements and sources

</tbody>
</table>

#### Degradable Organic Carbon (DOC)

Degradable Organic Carbon represents the amount of organic carbon in the waste that can be degraded. The final DOC value is calculated using the fraction of the total mass of the waste and multiplying it with the DOC fractions.

**Equation 3**

\[
DOC = (0.15 \times A) + (0.2 \times B) + (0.4 \times C) + (0.43 \times D) + (0.24 \times E) + (0.15 \times F)
\]

Emission Factors
Under this method the solid waste disposal emission factor (EF) is a combination of two factors, the methane generation potential ($L_0$) and the oxidation factor (OX). In the absence of data on facility-specific emission factors, this methodology relies on the default factor for OX derived from IPCC (2006).

\[ EF = L_0 * (1 - OX) \]

General Assumptions & Limitations

Mass of Waste
• Mass of waste generated, measured as the amount of waste disposed in landfills in Indonesia is proportionally related to population.
• All waste measured is categorized under scope 3 as we do not have the data to measure scope 1 emissions

Emission Factors

Methane Correction Factor
• Landfill sites assumed to fall under managed and unmanaged shallow anaerobic IPCC landfill characteristic are assigned an MCF of 1.0 and 0.4. Since there is no information on the type of Landfills in Indonesia a weighted MCF is created by taking the average of the above.

Methane Recovery
• Ministry of Public Works does not provide information for methane recovered therefore methane recovery is not reported.
